Presented at the European Congress of Rheumatology (EULAR), June 12–15, 2024, Vienna, Austria

OBJECTIVE

• To describe the long-term integrated safety profile of upadacitinib (UPA) 15 mg across indications in rheumatology, in the context of active comparators, from the SELECT clinical program

INTRODUCTION

- UPA, an oral JAK inhibitor, has demonstrated efficacy and safety across several rheumatic diseases, including RA, PsA, AS (also called r-axSpA), and nr-axSpA
- Safety observed with JAK inhibition to date has highlighted the need to further characterize the long-term safety profile of individual JAK inhibitors across diverse patient populations and in the context of active comparators, such as adalimumab (ADA) and MTX

METHODS

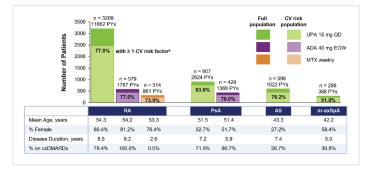

- Safety data (cutoff date: 15 August 2023) from eleven phase 3 UPA trials were compiled for RA (6), PsA (2), AS (2; one phase 2/3), and nr-axSpA (1) for this analysis^{1,2}
- Treatment-emergent adverse events (TEAEs) with an onset on or after the first dose of study drug and ≤ 30 days after the last dose of study drug for UPA 15 mg and MTX, or ≤ 70 days for ADA, were coded using MedDRA version 26.0
- TEAEs were summarized for RA (pooled UPA 15 mg, ADA, and MTX [1 study each with ADA or MTX as comparator]), PsA (pooled UPA 15 mg and ADA [1 study as comparator]), AS (pooled UPA 15 mg), nr-axSpA (UPA 15 mg), and pooled axSpA (pooled UPA 15 mg from AS and nr-axSpA trials)
- TEAEs are presented as exposure-adjusted event rates (EAERs; events/100 patient-years [E/100 PY]) with 95% CIs; patients were not censored at the time of first event and multiple events in the same patient were accounted for
- Deaths (including COVID-19), MACE, VTE, and gastrointestinal perforations were adjudicated by blinded, independent committees using pre-specified definitions
- Age-gender adjusted standard incidence ratios (SIRs) using the SEER 18 database (2000-2018) and country-age-gender adjusted standardized mortality ratios (SMRs) using the World Health Organization 2016 data were calculated

RESULTS

PATIENTS

- In total, 4998 patients received ≥ 1 dose of UPA 15 mg, totaling 15,895.8 PYs of exposure (Figure 1)
- Baseline demographics and clinical characteristics are representative of the patient populations; most patients (range: 74%–84%) had ≥ 1 cardiovascular (CV) risk factor

Figure 1. Baseline Demographics and Clinical Characteristics

ADA, adalimumab; csDMARDs, conventional synthetic DMARDs; CV, cardiovascular; EOW, every other week; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; PY, patient-years; QD, once daily; UPA, upadacitinib. ^aCV risk factors include: prior CV event, hypertension, diabetes mellitus, current and former tobacco/nicotine use, elevated LDL-C (≥ 3.36 mmol/L), and lowered HDL-C (≤ 1.034 mmol/L).

OVERVIEW OF TEAEs AND DEATHS

- The rate of adverse events (AEs) leading to discontinuation of study drug was generally similar across treatment groups and diseases (Table 1)
 - Types of AEs leading to discontinuation varied widely; the most frequently reported with UPA 15 mg were pneumonia (RA; n = 22/459), COVID-19 (PsA; n = 7/121), headache (AS; n = 3/42), and worsening axial spondyloarthritis and pulmonary embolism (nr-axSpA; both n = 2/20)
- Rates of treatment-emergent death were numerically higher with UPA 15 mg vs comparators in RA and PsA; rates of treatment-emergent COVID-19-related death ranged from 0.0 to 0.2 and CV death ranged from 0.0 to 0.2
- The SMR (95% CI) for treatment-emergent deaths with UPA 15 mg was 0.79 (0.63–0.98) in RA and 0.94 (0.59–1.40) in PsA; SMRs not calculated for AS or nr-axSpA (low events)

Table 1. TEAEs in Patients Treated With UPA, ADA, or MTX Across RA, PsA, AS, nr-axSpA, and Pooled axSpA

	RA			PsA		AS	nr-axSpA	Pooled axSpA

^bWith UPA 15 mg treatment, there were a total of 103 deaths in RA, 23 in PsA, 1 in AS, and 0 in nr-axSpA.

RESULTS (CONTINUED)

TEAEs AND AEs OF SPECIAL INTEREST (AESI)

- Rates of serious infection and opportunistic infection were generally similar across treatment groups and diseases; however, the rate of serious infection was numerically higher with UPA 15 mg vs ADA in PsA (Figure 2)
- COVID-19 pneumonia was both the most common serious infection and serious AE with UPA 15 mg treatment for all diseases
 - Overall, most patients with COVID-19 infection treated with UPA 15 mg had a mild or moderate case (range: 81.1%–93.2%), with 65.8% to 77.1% having study drug interrupted, but rarely withdrawn (≤ 5.5%)
- Numerically higher rates of herpes zoster (HZ) and elevated creatinine phosphokinase (CPK), which are known risks for JAK inhibitors, were reported with UPA 15 mg vs active comparators in RA and PsA
 - Most treatment-emergent events of HZ with UPA 15 mg were nonserious (RA: 96%; PsA: 98%; AS: 97%; nr-axSpA: 100%) and involved a single dermatome (RA: 76%; PsA: 74%; AS: 87%; nr-axSpA: 80%)

- Rates of malignancy excluding nonmelanoma skin cancer (NMSC) were generally similar across treatment groups and diseases; numerically higher rates of NMSC were observed with UPA 15 mg vs active comparators in RA and PsA
 - Basal cell carcinoma was the most common type of malignancy reported with UPA 15 mg treatment in RA (25 events) and PsA (14 events), with few events reported in AS (3) or nr-axSpA (1)
- The SIR (95% CI) for malignancy excluding NMSC with UPA 15 mg was 1.13 (0.94–1.36) in RA and 1.19 (0.75–1.78) in PsA
- Similar rates of MACE and VTE were observed across treatment groups and diseases; most events occurred in patients with ≥ 1 baseline CV risk factor
 - An increased risk of MACE, VTE, and malignancy excluding NMSC has been reported in RA patients with higher CV risk (aged ≥ 50 years and ≥ 1 CV risk factor) compared to the overall RA population, with risk being generally similar between UPA and ADA⁵

Figure 2. TEAEs and AEs of Special Interest in Patients Treated With UPA Across RA, PsA, AS, nr-axSpA, and Pooled axSpA^a

AE, adverse event; ADA, adalimumab; CPK, creatine phosphokinase; E, event; EAER, exposure-adjusted event rate; EAIR, exposure-adjusted incidence rate; EMM, extra-musculoskeletal manifestation; EOW, every other week; GI, gastrointestinal; IBD, inflammatory bowel disease; NMSC, nonmelanoma skin cancer; PY, patient-years; QD, once daily; TEAE, treatment-emergent adverse event; UPA, upadacitinib.

^aUPA sample sizes include patients who switched from placebo and received 1 dose of upadacitinib; data are presented as EAERs, defined as E/100 PY (95% CI) [number of events] and EAER data were not censored. ^bOpportunistic infections excluding tuberculosis and herpes zoster. ^cPer the protocol, CPK elevation was not measured in the nr-axSpA study. ^cCases of abnormal lymphocyte morphology are included (UPA 15 mg: RA [1], PsA [3], AS [1], and nr-axSpA [1]), as this preferred term is included in the Malignant Lymphoma Standardized MedDRA Queries, but these events were not confirmed to be true lymphomas. ^eMACE was defined as nonfatal myocardial infarction, nonfatal stroke, and cardiovascular death. ¹VTE includes deep vein thrombosis (DVT) and pulmonary embolism (PE) (fatal and non-fatal). ^aIBD includes inflammatory bowel disease, colitis ulcerative, ulcerative colitis, colitis, Crohn's disease, ulcerative proctitis; uveitis includes uveitis, iritis, and iridocyclitis; neither IBD or uveitis data were captured for RA.

CONCLUSIONS

- With the exception of serious infection (in PsA), HZ, elevated creatine phosphokinase, and NMSC, the rates of TEAEs were generally similar between UPA 15 mg and active comparators (ADA and MTX) in RA and PsA
- Across RA, PsA, AS, and nr-axSpA, UPA 15 mg demonstrated a generally consistent safety profile, with no new safety risks identified with long-term treatment, as shown in previous reports^{1,3,4}
- Real-world data, especially for diseases with more limited clinical trial exposure (ie, AS and nr-axSpA), are needed to further contextualize and confirm these findings
